

AI Validation for our project.

While building our website, we used AI as a tool to really understand how things work, not just to get answers. With CSS, it helped us figure out tricky layouts and properties, and also made autocompleting repetitive stuff way faster—without doing the work for us. That way, we could focus on designing and experimenting while actually learning the fundamentals.

An example prompt was “How do have different CSS priority within a file”

For JavaScript, AI was great for breaking down concepts like event handling, DOM manipulation, and async functions. It gave us guidance on how to structure our code and reduce repetition, but we still wrote everything ourselves. This helped us make interactive and responsive features while keeping our coding skills sharp.

On the backend, AI helped us get a grip on how servers, databases, and APIs work together. It explained request handling, data flow, and security in ways that made sense, letting us write functional backend code ourselves. Using it this way meant we could build a full web app from start to finish, learning as we went and keeping full control of the project.
